

Objects for the Masses

Marcus Börger

PHP Quebec 09: <http://talks.somabo.de/200903.pdf> | .pps

Overview

- 3 What is OOP?
- 25 PHP & OOP
- 29 PHP OOP In Detail
- 48 Class Design
- 50 Dynamic Class Loading
- 55 Exceptions
- 77 Reflection
- 80 Built-in Interfaces
- 108 Design Patterns

What is OOP

```
class Useless extends Nonsense
{
    abstract function blaBla();
}
```

What does OOP aim to achieve?

- þ Allow compartmentalized refactoring of code.
- þ Promote code re-use.
- þ Promote extensibility, flexibility and adaptability.
- þ Better for team development.
- þ Many patterns are designed for OOP.
- þ Some patterns lead to much more efficient code.

- þ Do you need to use OOP to achieve these goals?
 - þ Of course not.
 - þ It's designed to make those things easier though.

What are the features of OOP?

- þ Encapsulation
- þ Inheritance
- þ Polymorphism

Encapsulation

þ

Encapsulation is about grouping of functionality (operations) and related data (attributes) together into a coherent data structure (classes).

Encapsulation

þ

Encapsulation is about grouping of functionality (operations) and related data (attributes) together into a coherent data structure (classes).

þ

Classes represent complex data types and the operations that act on them. An object is a particular instance of a class.

Encapsulation

- þ Encapsulation is about grouping of functionality (operations) and related data (attributes) together into a coherent data structure (classes).
- þ Classes represent complex data types and the operations that act on them. An object is a particular instance of a class.
- þ **The basic idea is to re-code real life.**
For instance, if you press a key on your laptop keyboard you do not know what is happening in detail. For you it is the same as if you press the keyboard of an ATM. We say the interface is the same. If another person has the same laptop the internal details would be exactly the same.

Encapsulation

- þ Encapsulation is about grouping of functionality (operations) and related data (attributes) together into a coherent data structure (classes).
- þ Classes represent complex data types and the operations that act on them. An object is a particular instance of a class.
- þ **The basic idea is to re-code real life.**
For instance, if you publish a text that is not really different from publishing a picture. Both are content types and you might want to encapsulate the details on how to do the actual publishing in a class. And once you have that you can easily have content that consists of both pictures and text and yet use the same operations for publishing. Then later you might publish tables using the same interface.

Encapsulation: Are Objects Just Dictionaries?

- þ In PHP 4 objects were little more than arrays.
- þ In PHP 5 you get much more control by visibility, interfaces, type hints, interceptors and more.
- þ Another difference is coherency. Classes can be told to automatically execute specific code on object creation and destruction.

```
class Simple {  
    function __construct() { /*...*/ }  
    function __destruct() { /*...*/ }  
}
```

Data Hiding

þ

Another difference between objects and arrays is that objects permit strict visibility semantics. Data hiding eases refactoring by controlling what other parties can access in your code.

- þ **public** anyone can access it
- þ **protected** only descendants can access it
- þ **private** only you can access it
- þ **final** no one can re-declare it
- þ **abstract** someone else will implement this

Why have these in PHP?

Because sometimes self-discipline isn't enough.

Inheritance

- þ Inheritance allows a class to specialize (or extend) another class and inherit all its methods, properties and behaviors.
- þ This promotes
 - þ Extensibility
 - þ Reusability
 - þ Code Consolidation
 - þ Abstraction
 - þ Responsibility

The Problem of Code Duplication

Code duplication contradicts maintainability.
You often end up with code that looks like this:

```
function foo_to_xml ($foo) {  
    // generic stuff  
    // foo-specific stuff  
}
```

```
function bar_to_xml ($bar) {  
    // generic stuff  
    // bar specific stuff  
}
```

The Problem of Code Duplication

You could clean that up as follows

```
function base_to_xml ($data) { /*...*/ }
function foo_to_xml ($foo) {
    base_to_xml ($foo);
    // foo specific stuff
}
function bar_to_xml ($bar) {
    base_to_xml ($bar);
    // bar specific stuff
}
```

But it's hard to keep `base_to_xml()` working for the disparate `foo` and `bar` types.

The Problem of Code Duplication

- þ In an OOP style you would create classes for the Foo and Bar classes that extend from a base class that handles common functionality.
- þ Sharing a base class promotes sameness.

```
class Base {  
    public function toXML()  
    {  
        /*...*/  
    }  
}  
  
class Foo extends Base {  
    public function toXML()  
    {  
        parent::toXML();  
        // foo specific stuff  
    }  
}  
  
class Bar extends Base {  
    public function toXML()  
    {  
        parent::toXML();  
        // bar specific stuff  
    }  
}
```

Marcus Börger Objects for the Masses

Polymorphism?

þ

Suppose a calendar that is a collection of entries.
Procedurally displaying all the entries might look like:

```
foreach($entries as $entry) {  
    switch($entry['type']) {  
        case 'professional':  
            display_professional_entry($entry);  
            break;  
        case 'personal':  
            display_personal_entry($entry);  
            break;  
    }  
}
```

Simplicity through Polymorphism

In the OOP paradigm this would look like:

```
foreach($entries as $entry) {  
    $entry->display();  
}
```

The key point is we don't have to modify this loop to add new types. When we add a new type, that type gets a `display()` method so that it knows how to display itself, and we're done.

Also this is much faster because we do not have to check the type for every element.

Simplicity through Magic?

Actually in PHP you might want this:

```
foreach($entries as $entry) {  
    echo $entry;  
}
```

A class can have a `__toString()` method which defines how its objects are converted into a textual representation.

PHP 5.2 supports this in all string contexts.

Polymorphism the other way round

þ

Unlike other languages PHP does not and will not offer polymorphism for method calling. Thus the following will never be available in PHP

```
<?php
class Test {
    function toXML(Personal $obj) //...
    function toXML(Professional $obj) //...
}
?>
```

þ

To work around this

- þ Use the other way round (call other methods from a single toXML() function in a polymorphic way)
- þ Use switch/case (though this is not the OO way)

Another example

```
class Humans {  
    public function __construct($name) {  
        /*...*/  
    }  
    public function eat() { /*...*/ }  
    public function sleep() { /*...*/ }  
    public function snore() { /*...*/ }  
    public function wakeup() { /*...*/ }  
}
```

Some Inheritance

```
class Humans {  
    public function __construct($name) { /*... */}  
    public function eat() { /*... */}  
    public function sleep() { /*... */}  
    public function snore() { /*... */}  
    public function wakeup() { /*... */}  
}  
class Women extends Humans {  
    public function giveBirth() { /*... */}  
}
```

Inheritance + Polymorphism

```
class Humans {  
    public function __construct($name) { /*...*/ }  
    public function eat() { /*...*/ }  
    public function sleep() { /*...*/ }  
    public function wakeup() { /*...*/ }  
}  
class Women extends Humans {  
    public function giveBirth() { /*...*/ }  
}  
class Men extends Humans {  
    public function snore() { /*...*/ }  
}
```

A little abstraction

```
abstract class Humans {  
    public function __construct($name) { /*...*/ }  
    abstract public function gender();  
    public function eat() { /*...*/ }  
    public function sleep() { /*...*/ }  
    public function wakeup() { /*...*/ }  
}  
class Women extends Humans {  
    public function gender() { return 'female'; }  
    public function giveBirth() { /*...*/ }  
}  
class Men extends Humans {  
    public function gender() { return 'male'; }  
    public function snore() { /*...*/ }  
}
```

A little abstraction

```
abstract class Humans {  
    public function __construct($name) { /*...*/ }  
    abstract public function gender();  
    public function eat() { /*...*/ }  
    public function sleep() { /*...*/ }  
    public function wakeup() { /*...*/ }  
}  
class Women extends Humans {  
    final public function gender() { return 'f'; }  
    public function giveBirth() { /*...*/ }  
}  
class Men extends Humans {  
    final public function gender() { return 'm'; }  
    public function snore() { /*...*/ }  
}
```

PHP & OOP

..

PHP 4 and OOP ?

Poor Object model

þ Methods

- ÿ No visibility
- ÿ No abstracts, no final
- ÿ Static without declaration

þ Properties

- ÿ No static properties
- ÿ No constants

þ Inheritance

- ÿ No abstract, final inheritance, no interfaces
- ÿ No prototype checking, no types

þ Object handling

- ÿ Copied by value
- ÿ No destructors

ZE2's revamped object model

b

b

b

b

b

b

b

b

b

b

b

b

b

Objects are referenced by identifiers

Constructors and Destructors

Static members

Constants

Visibility

Interfaces

Final and abstract members

Interceptors

Exceptions

Reflection API

Iterators

Namespaces (5.3)

Closures (5.3) . . . Prototypes (5.4/6.0/never?)

Revamped Object Model

þ

- PHP 5 has really good OOP support
 - þ Better code reuse
 - þ Better for team development
 - þ Easier to refactor
 - þ Some patterns lead to much more efficient code
 - þ Fits better in marketing scenarios

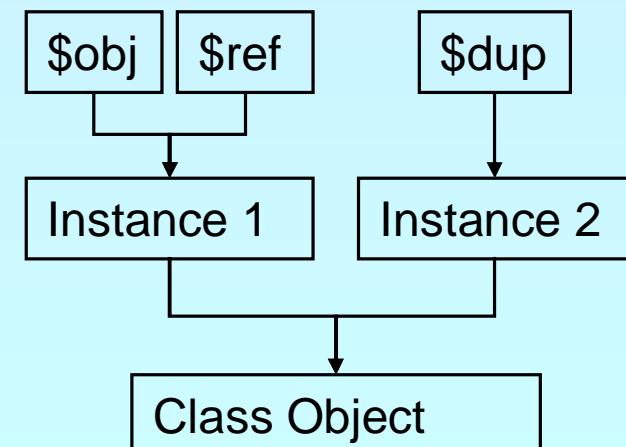

PHP 5 OOP In Detail

Objects referenced by identifiers

- þ Objects are no longer somewhat special arrays
- þ Objects are no longer copied by default
- þ Objects may be copied using `clone`/`__clone()`

```
class Object {};  
  
$obj = new Object();  
  
$ref = $obj;  
  
$dup = clone $obj;
```

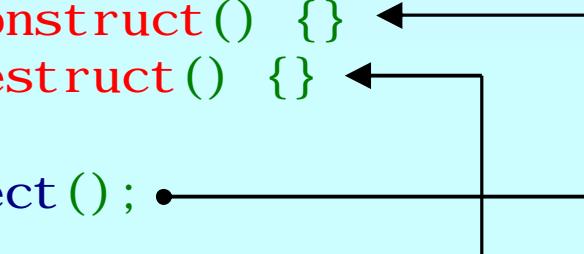

Constructors and Destructors

Constructors/Destructors control object lifetime

- þ Constructors may have both new OR old style name
 - þ New style constructors are preferred
 - þ Constructors must not use inherited protocol
- þ Destructors are called when deleting the last reference
 - þ No particular or controllable order during shutdown
 - þ Destructors cannot have parameters
 - þ Since PHP 5.0.1 destructors can work with resources

```
class Object {
    function __construct() {}
    function __destruct() {}
}
$obj = new Object();
unset($obj);
```

Constructors and Destructors

b

Parents must be called manually

```
class Base {  
    function __construct() {} ←  
    function __destruct() {} ←  
}  
class Object extends Base {  
    function __construct() { ←  
        parent::__construct(); • ←  
    }  
    function __destruct() { ←  
        parent::__destruct(); • ←  
    }  
}  
$obj = new Object(); • ←  
unset($obj); • ←
```

Default property values

-

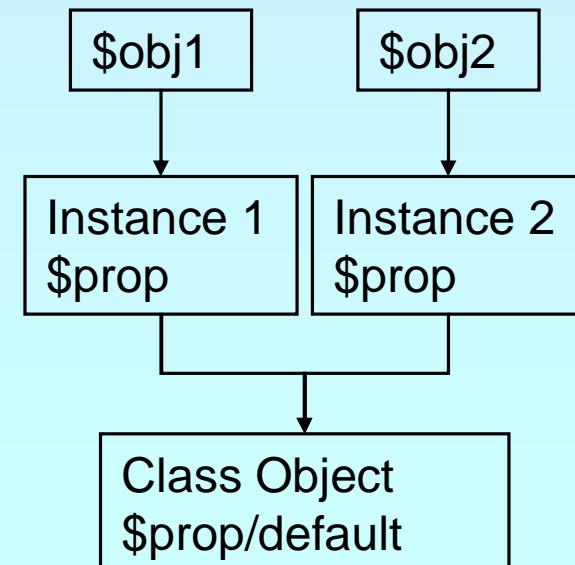

Properties can have default values

- Bound to the class not to the object
- Default values cannot be changed but overwritten

```
class Object {
    var $prop = "Hello\n";
}

$obj1 = new Object;
$obj1->prop = "Hello World\n";

$obj2 = new Object;
echo $obj2->prop; // Hello
```

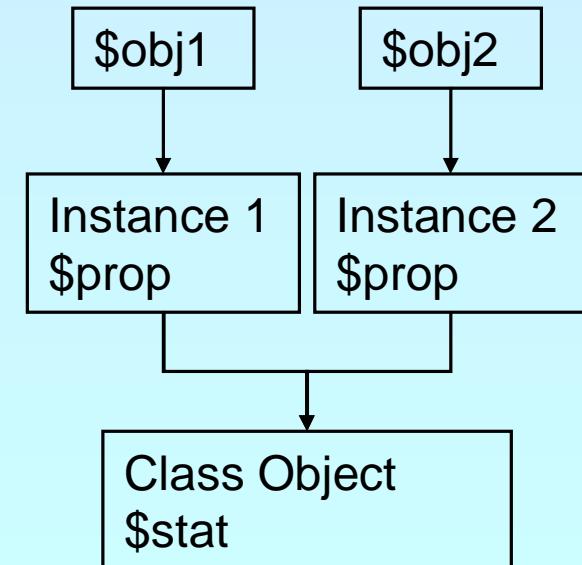

Static members

þ

Static methods and properties

- þ Bound to the class not to the object
 - þ Only exists once per class rather than per instance
- þ Can be initialized

```
class Object {
    var $prop;
    static $stat = "Hello\n";
    static function test() {
        echo self::$stat;
    }
}
Object::test();
$obj1 = new Object;
$obj2 = new Object;
```

Pseudo constants

þ __CLASS__

shows the current class name

þ __METHOD__

shows class and method or function

þ self

references the class itself

þ parent

references the parent class

þ \$this

references the object itself

```
class Base {
    static function Show() {
        echo __FILE__. '(' . __LINE__. ')'. __METHOD__. "\n";
    }
}
class Object extends Base {
    static function Use() {
        Self::Show();
        Parent::Show();
    }
    static function Show() {
        echo __FILE__. '(' . __LINE__. ')'. __METHOD__. "\n";
    }
}
```

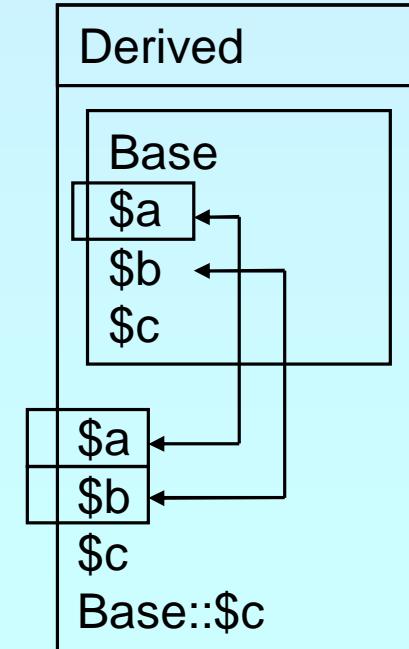

Visibility

- þ

Controlling member visibility / Information hiding

- þ A derived class doesn't know parents private members
- þ An inherited protected member can be made public

```
class Base {  
    public $a;  
    protected $b;  
    private $c;  
}  
  
class Derived extends Base {  
    public $a;  
    public $b;  
    private $c;  
}
```

Constructor visibility

- A protected constructor prevents instantiation

```
class Base {  
    protected function __construct() {  
    }  
}  
  
class Derived extends Base {  
    // constructor is still protected  
    static function getBase() {  
        return new Base; // Factory pattern  
    }  
}  
  
class Three extends Derived {  
    public function __construct() {  
    }  
}
```

The Singleton pattern

Sometimes you want only a single instance of a class to ever exist.

DB connections

An object representing the user or connection.

```
class Singleton {
    static private $instance;
    protected function __construct() {}
    final private function __clone() {}
    static function getInstance() {
        if (!self::$instance)
            self::$instance = new Singleton();
        return self::$instance;
    }
}
$a = Singleton::getInstance();
$a->id = 1;
$b = Singleton::getInstance();
print $b->id. "\n";
```

Constants

- Constants are read only static properties
- Constants are always public

```
class Base {  
    const greeting = "Hello\n";  
}
```

```
class Derived extends Base {  
    const greeting = "Hello World\n";  
    static function func() {  
        echo parent::greeting;  
    }  
}
```

```
echo Base::greeting;  
echo Derived::greeting;  
Derived::func();
```

Abstract members

- þ Methods can be abstract
 - þ They don't have a body
 - þ A class with an abstract method must be abstract
- þ Classes can be made abstract
 - þ The class cannot be instantiated
- þ Properties cannot be made abstract

```
abstract class Base {  
    abstract function no_body();  
}  
  
class Derived extends Base {  
    function no_body() { echo "Body\n"; }  
}
```

Final members

- þ Methods can be final
 - þ They cannot be overwritten
 - þ They are class invariants
- þ Classes can be final
 - þ They cannot be inherited

```
class Base {  
    final function invariant() { echo "Hello\n"; }  
}  
  
class Derived extends Base {  
}  
  
final class Leaf extends Derived {  
}
```

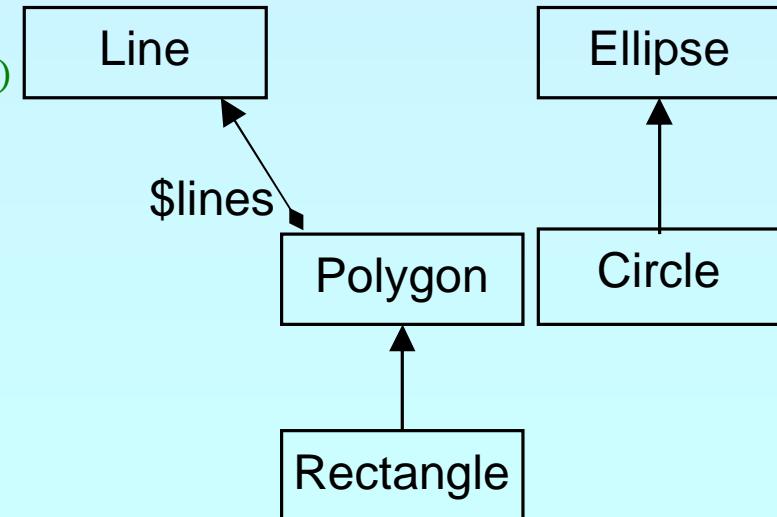

þ

Different Object same behavior

Often different objects have the same interface
without having the same base class

```
class Line {
    function draw() {};
}
class Polygon {
    protected $lines;
    function draw() {
        foreach($this->lines as $line)
            $line->draw();
    }
}
class Rectangle extends Polygon {
}
class Ellipse {
    function draw() {};
}
class Circle extends Ellipse {
    function draw() {
        parent::draw();
    }
}
```

Interfaces

þ
þ

Interfaces describe an abstract class protocol
Classes may inherit multiple Interfaces

```
interface Drawable {
    function draw();
}

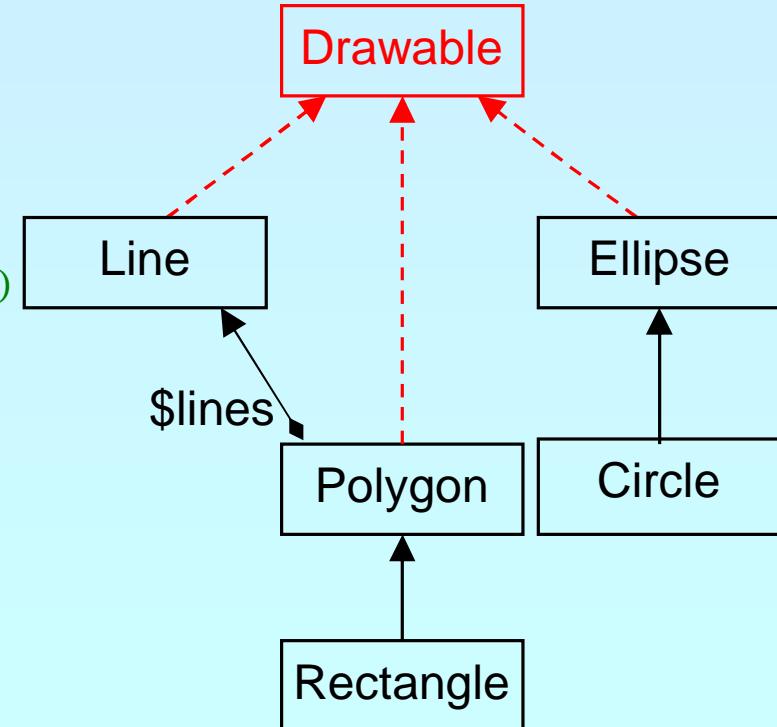

class Line implements Drawable {
    function draw() {};
}

class Polygon implements Drawable {
    protected $lines;
    function draw() {
        foreach($this->lines as $line)
            $line->draw();
    }
}

class Rectangle extends Polygon {}

class Ellipse implements Drawable {
    function draw() {};
}

class Circle extends Ellipse {
    function draw() {
        parent::draw();
    }
}
```

Property kinds

Declared properties

- ↳ May have a default value
- ↳ Can have selected visibility

Implicit public properties

- ↳ Declared by simply using them in ANY method

Virtual properties

- ↳ Handled by interceptor methods

Static properties

- ↳ Bound to the class rather than to the instance

Object to String conversion

þ

`__toString()`: semi-automatic object to string conversion with echo and print (automatic starting with 5.2)

```
class Object {
    function __toString() {
        return 'Object as string';
    }
}

$o = new Object;

echo $o;          // does call __toString

$str = (string) $o; // does call __toString
```

Interceptors

- þ Allow to dynamically handle non class members
 - þ Lazy initialization of properties
 - þ Simulating Object aggregation and Multiple inheritance

```
class Object {
    protected $virtual = array();
    function __get($name) {
        return @$this->virtual[$name];
    }
    function __set($name, $value) {
        $this->virtual[$name] = $value;
    }
    function __unset($name) {
        unset($this->virtual[$name]);
    }
    function __isset($name) {
        return isset($this->virtual[$name]);
    }
    function __call($func, $params) {
        echo 'Could not call ' . __CLASS__ . '::' . $func . "\n";
    }
}
```

Typehinting

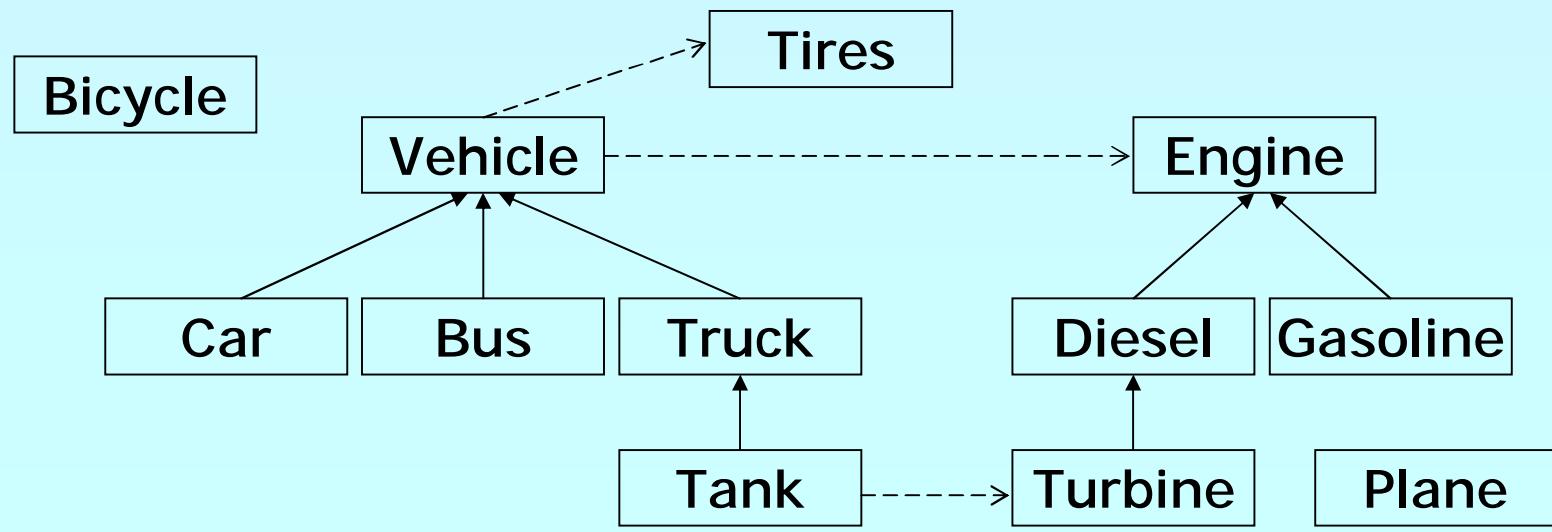

- þ PHP 5 allows to easily force a type of a parameter
 - þ PHP does not allow NULL for typehints
 - þ Typehints must be inherited as given in base class
 - þ PHP 5.1 offers typehinting with arrays
 - þ PHP 5.2 offers optional typehinted parameters (= NULL)

```
class Object {  
    public function compare(Object $other) {  
        // Some code here  
    }  
    public function compare2($other) {  
        if (is_null($other) || $other instanceof Object) {  
            // Some code here  
        }  
    }  
}
```

Class Design

- It is important to think about your class hierarchy
- Avoid very deep or broad inheritance graphs
- PHP only supports **is-a** and **has-a** relations

Too Strict or too Weak?

- þ PHP tries to prevent you from doing some errors
 - þ You are bound to keep inherited signatures
 - þ You cannot change from ref to non-ref return

- þ Yet PHP allows absolute flexibility
 - þ Just do not define a signature
 - þ **Warning: This is extremely error prone**

Dynamic Class Loading

Dynamic class loading

þ

`__autoload()` is good **when you're alone**

- þ Requires a single file for each class
- þ Only load class files when necessary
 - þ No need to parse/compile unneeded classes
 - þ No need to check which class files to load

ý Additional user space code

N Only one single loader model is possible

__autoload & require_once

þ

Store the class loader in an include file

þ In each script:

```
require_once(' <path>/autoload.inc' )
```

þ Use INI option:

```
auto-prepend_file=<path>/autoload.inc
```

```
<?php
function __autoload($class_name)
{
    require_once(
        dirname(__FILE__) . '/' . $class_name . '.p5c');
}
?>
```

SPL's class loading

- þ Supports fast default implementation
 - þ Look into path's specified by INI option `include_path`
 - þ Look for specified file extensions (.inc, .php)
- þ Ability to register multiple user defined loaders
- þ Overwrites ZEND engine's `__autoload()` cache
 - þ You need to register `__autoload` if using spl's autoload

```
<?php
    spl_autoload_register('spl_autoload');
    if (function_exists('__autoload')) {
        spl_autoload_register('__autoload');
    }
?>
```

SPL's class loading

- þ `spl_autoload($class_name, $extensions=NULL)`
Load a class from a file in include path
Fast C code implementation
- þ `spl_autoload_extensions($extensions=NULL)`
Get or set filename extensions
- þ `spl_autoload_register($loader_function)`
Register a single loader function
- þ `spl_autoload_unregister($loader_function)`
Unregister a single loader function
- þ `spl_autoload_functions()`
List all registered loader functions
- þ `spl_autoload_call($class_name)`
Load a class through registered class loaders
Uses `spl_autoload()` as fallback

Exceptions

Exceptions

b

Respect these rules

1. Exceptions are exceptions
2. Never use exceptions for control flow
3. Never ever use exceptions for parameter passing

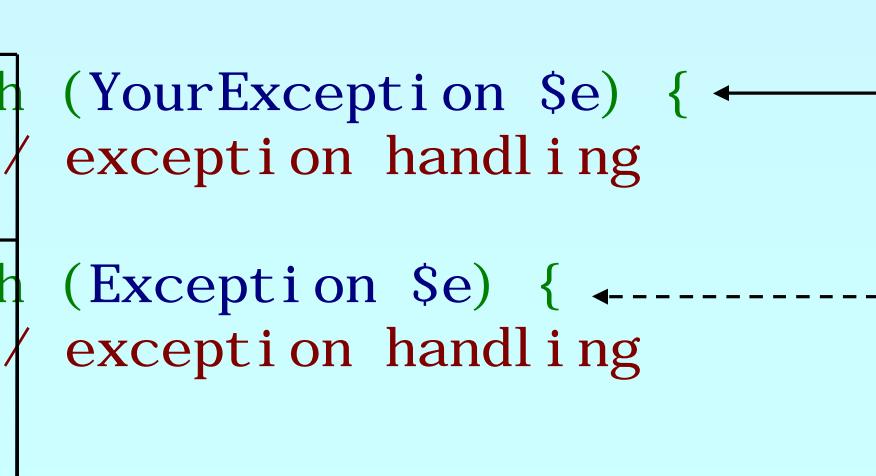

```
<?php
try {
    // your code
    throw new Exception();
}
catch (Exception $e) {
    // exception handling
}
?>
```

Exception specialization

- Exceptions should be specialized
- Exceptions should inherit built in class exception

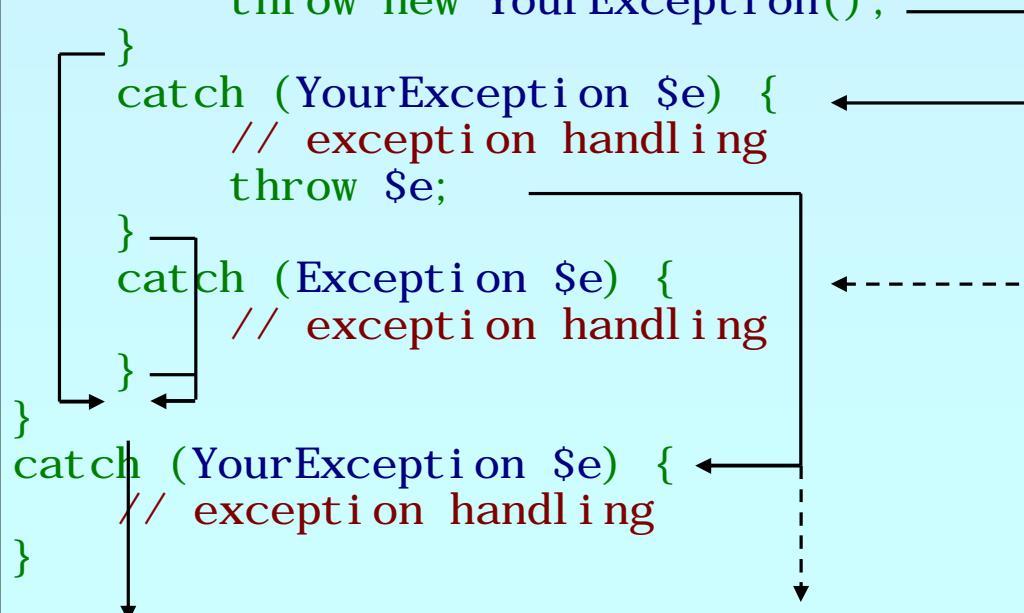

```
class YourException extends Exception {  
}  
try {  
    // your code  
    throw new YourException();  
}  
catch (YourException $e) { ←  
    // exception handling  
}  
catch (Exception $e) { ←-----  
    // exception handling  
}
```

Exception specialization

- Exception blocks can be nested
- Exceptions can be re thrown

```
class YourException extends Exception {}  
try {  
    try {  
        // your code  
        throw new YourException();  
    }  
    catch (YourException $e) {  
        // exception handling  
        throw $e;  
    }  
    catch (Exception $e) {  
        // exception handling  
    }  
}  
catch (YourException $e) {  
    // exception handling  
}
```

Practical use of exceptions

- þ Constructor failure
- þ Converting errors/warnings to exceptions
- þ Simplify error handling
- þ Provide additional error information by tagging

Constructor failure

- þ In PHP 4.4 you would simply `unset($this)`
- þ Provide an argument to receive the error condition

```
<?php
class Object
{
    function __construct( &$failure) // "Object" in PHP 4
    {
        $failure = true;
    }
}
$error = false;
$o = new Object($error);
if (!$error) {
    // error handling, NOTE: the object was constructed
    unset($o);
}
?>
```

Constructor failure

- þ In 5 constructors do not return the created object
- þ Exceptions allow to handle failed constructors

```
<?php
class Object
{
    function __construct()
    {
        throw new Exception();
    }
}
try {
    $o = new Object();
}
catch (Exception $e) {
    echo "Object could not be instantiated\n";
}
?>
```

Convert Errors to Exceptions

þ

Implementing PHP 5.1 class ErrorException

```
<?php
if (!class_exists('ErrorException', false)) {
    class ErrorException extends Exception
    {
        protected $severity;
        function __construct($msg, $code, $errno, $file, $line)
        {
            parent::__construct($msg, $code);
            $this->severity = $errno;
            $this->file = $file;
            $this->line = $line;
        }
        function getSeverity() {
            return $this->severity;
        }
    }
}
?>
```

Convert Errors to Exceptions

þ

Implementing the error handler

```
<?php

function ErrorsToExceptions($errno, $msg, $file, $line)
{
    throw new ErrorException($msg, 0, $errno, $file, $line);
}

set_error_handler('ErrorsToExceptions');

?>
```

Simplify error handling

Typical database access code contains lots of if's

```
<html><body>
<?php
$ok = false;
$db = new PDO(' CONNECTION ');
if ($db) {
    $res = $db->query(' SELECT data ');
    if ($res) {
        $res2 = $db->query(' SELECT other ');
        if ($res2) {
            // handle data
            $ok = true; // only if all went ok
        }
    }
}
if (! $ok) echo '<h1>Service currently unavailable</h1>';
?>
</body></html>
```

Simplify error handling

þ

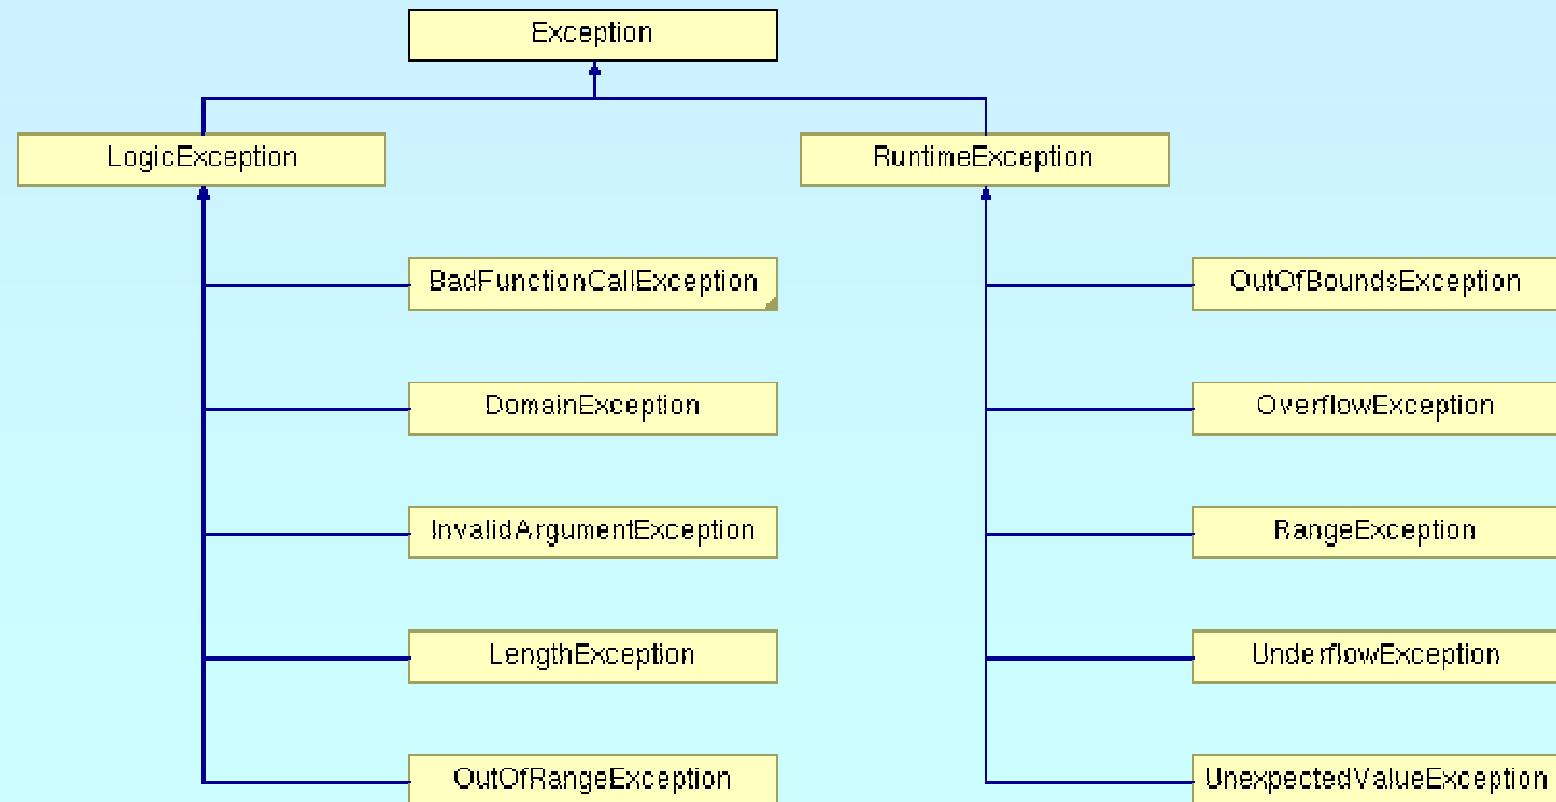

Trade code simplicity with a new complexity

```
<html><body>
<?php
try {
    $db = new PDO(' CONNECTION ');
    $db->setAttribute(PDO::ATTR_ERRMODE,
                      PDO::ERRMODE_EXCEPTION);
    $res = $db->query(' SELECT data ');
    $res2 = $db->query(' SELECT other ');
    // handle data
}
catch (Exception $e) {
    echo '<h1>Service currently unavailable</h1>';
    error_log($e->getMessage());
}
?>
</body></html>
```

SPL Exceptions

- ↳ SPL provides a standard set of exceptions
- ↳ Class Exception **must** be the root of all exceptions

General distinguishing

þ

LogicException

- è Anything that could have been detected at compile time, during application design or by the good old technology:
"look closely"

þ

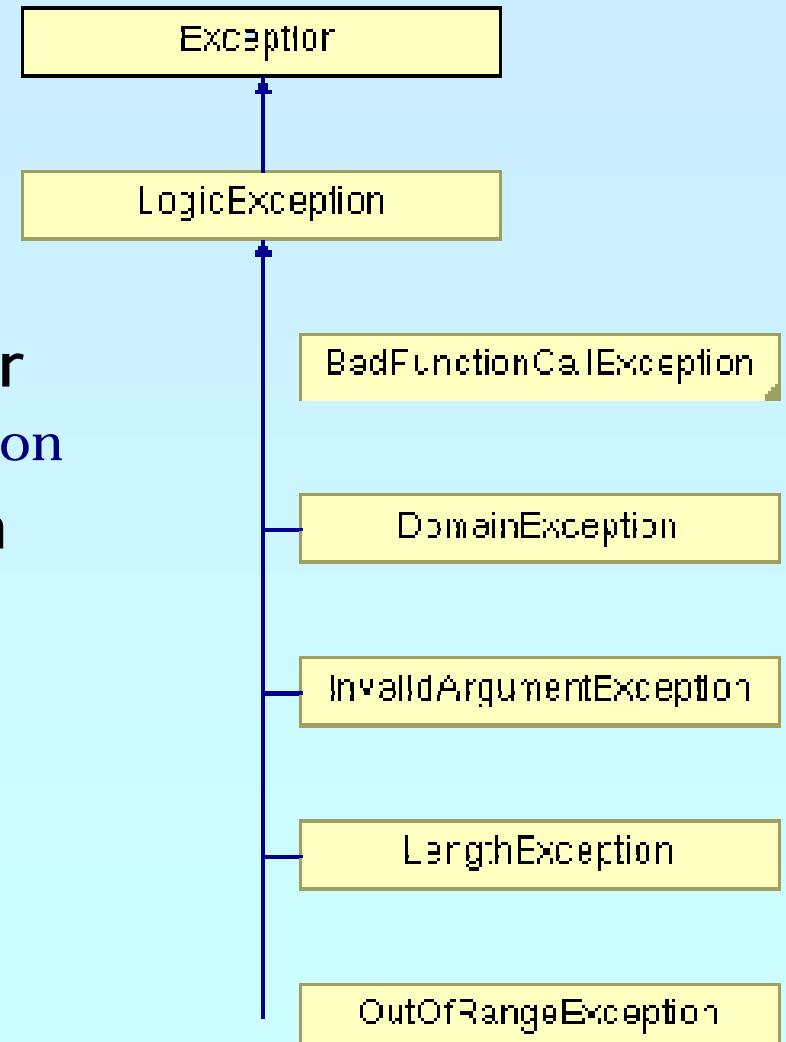

RuntimeException

- è Anything that is unexpected during runtime
- è Base Exception for all database extensions

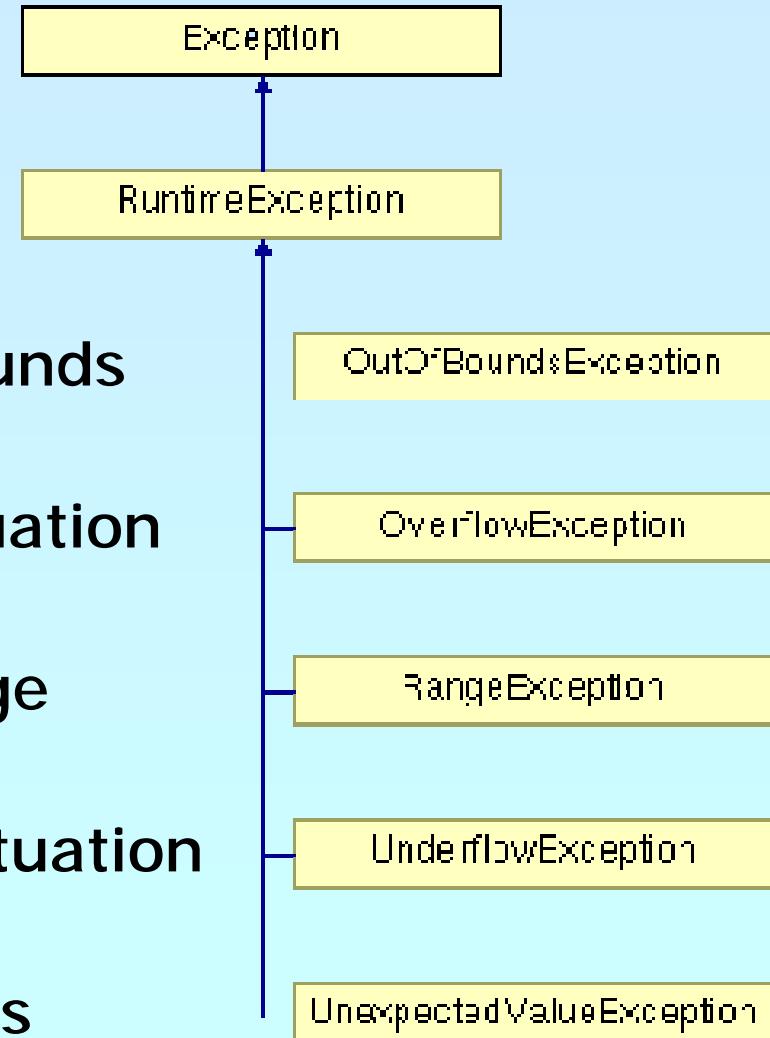

LogicException

- þ Function not found or similar
BadMethodCallException
- þ Value not in allowed domain
- þ Argument not valid
- þ Length exceeded
- þ Some index is out of range

RunTimeException

- þ An actual value is out of bounds
- þ Buffer or other overflow situation
- þ Value outside expected range
- þ Buffer or other underflow situation
- þ Any other unexpected values

Overloading __call

- ¶ If using __call, ensure only valid calls are made

```
abstract class MyIteratorWrapper implements Iterator
{
    function __construct(Iterator $it)
    {
        $this->it = $it;
    }
    function __call($func, $args)
    {
        $callee = array($this->it, $func);
        if (!is_callable($callee)) {
            throw new BadMethodCallException();
        }
        return call_user_func_array($callee, $args);
    }
}
```

Compile-Time:
Error in design

Interfaces and __call

þ
þ

Interface functions cannot be handled by __call
Either mark the class abstract...

```
abstract class MyIteratorWrapper implements Iterator
{
    function __construct(Iterator $it)
    {
        $this->it = $it;
    }
    function __call($func, $args)
    {
        $callee = array($this->it, $func);
        if (!is_callable($callee)) {
            throw new BadMethodCallException();
        }
        return call_user_func_array($callee, $args);
    }
}
```

```
Interface Iterator {
    function rewind();
    function valid();
    function current();
    function key();
    function next();
```

Interfaces and __call

- Interface functions cannot be handled by __call
- ...or provide the functions (here as proxy/forward)

```
class MyIteratorWrapper implements Iterator
{
    function __construct(Iterator $it)
    {
        $this->it = $it;
    }
    function __call($func, $args)
    {
        $callee = array($this->it, $func);
        if (!is_callable($callee)) {
            throw new BadMethodCallException();
        }
        return call_user_func_array($callee, $args);
    }

    function rewind() { $this->it->rewind(); }
    function valid() { return $this->it->valid(); }
    function current() { return $this->it->current(); }
    function key() { return $this->it->key(); }
    function next() { $this->it->next(); }
}

Interface Iterator {
    function rewind();
    function valid();
    function current();
    function key();
    function next();
}
```

Expecting formatted data

þ

Opening a file for reading

```
$fo = new SplFileObject($file);  
$fo->setFlags(SplFileObject::DROP_NEWLINE);  
$data = array();
```

Run-Time:

File might not be
accessible or exist

Expecting formatted data

þ

Reading a formatted file line by line

```
$fo = new SplFileObject($file);
$fo->setFlags(SplFileObject::DROP_NEWLINE);
$data = array();
foreach($fo as $l) {
    if (/*** CHECK DATA ***/)
        throw new Exception();
}
$data[] = $l;
}
```

Run-Time:

File might not be
accessible or exist

Run-Time:

data is different for
every execution

þ
þ
þ

```
!preg_match($regex, $l)
count($l = split(' ', $l)) != 3
count($data) > 100
```

UnexpectedValueException
RangeException
OverflowException

Expecting formatted data

þ

Checking data after pre-processing

```
$fo = new SplFileObject($file);  
$fo->setFlags(SplFileObject::DROP_NEWLINE);  
$data = array();  
foreach($fo as $l) {  
    if (!preg_match('/\d, \d/', $l)) {  
        throw new UnexpectedValueException();  
    }  
    $data[] = $l;  
}  
// Checks after the file was read entirely  
if (count($data) < 10) throw new UnderflowException();  
if (count($data) > 99) throw new OverflowException();  
if (count($data) < 10 || count($data) > 99)  
    throw new OutOfBoundsException();
```

Run-Time:

File might not be accessible or exist

Run-Time:

data is different for every execution

þ
þ
þ

Expecting formatted data

þ

Processing pre-checked data

```
$fo = new SplFileObject($file);
$fo->setFlags(SplFileObject::DROP_NEWLINE);
$data = array();
foreach($fo as $l) {
    if (!preg_match('/\d,\d/', $l)) {
        throw new UnexpectedValueException();
    }
    $data[] = $l;
}
if (count($data) < 10) throw new UnderflowException();
// maybe more processing code
foreach($data as &$v) {
    if (count($v) == 2) {
        throw new DomainException();
    }
    $v = $v[0] * $v[1];
}
```

The diagram consists of three callout boxes with arrows pointing to specific parts of the code:

- A grey box labeled "Run-Time: File might not be accessible or exist" points to the line `$fo = new SplFileObject($file);`
- A grey box labeled "Run-Time: data is different for every execution" points to the line `if (count($data) < 10) throw new UnderflowException();`
- A red box labeled "Compile-Time: exception signals failed precondition" points to the line `if (count($v) == 2) {`

Reflection

Reflection API

- þ Can reflect nearly all aspects of your PHP code
 - þ Functions
 - þ Classes, Methods, Properties
 - þ Extensions

```
class Foo {  
    public $prop;  
    function Func($name) {  
        echo "Hello $name";  
    }  
}
```

```
ReflectionClass::export('Foo');  
ReflectionObject::export(new Foo);  
ReflectionMethod::export('Foo', 'func');  
ReflectionProperty::export('Foo', 'prop');  
ReflectionExtension::export('standard');
```

Dynamic object creation

þ

Reflection allows dynamic object creation

```
class Test {  
    function __construct($x, $y = NULL) {  
        $this->x = $x;  
        $this->y = $y;  
    }  
}  
function new_object_array($cls, $args = NULL) {  
    return call_user_func_array(  
        array(new ReflectionClass($cls), 'newInstance'),  
        $args);  
}  
  
new_object_array('stdClass');  
new_object_array('Test', array(1));  
new_object_array('Test', array(1, 2));
```

Built-in Interfaces

Built-in Interfaces

- þ PHP 5 contains built-in interfaces that allow you to change the way the engine treats objects.
 - þ [ArrayAccess](#)
 - þ [Iterator](#)
 - þ [IteratorAggregate](#)
- þ Built-in extension SPL provides more Interfaces and Classes
 - þ [ArrayObject](#), [ArrayIterator](#)
 - þ [FilterIterator](#)
 - þ [RecursiveIterator](#)
- þ Use CLI:
`php --re SPL`
`php --rc ArrayAccess`

ArrayAccess

- Allows for creating objects that can be transparently accessed by array syntax.
- When combined with the iterator interface, it allows for creating 'arrays with special properties'.

```
interface ArrayAccess {  
    // @return whether $offset is valid (true/false)  
    function offsetExists($offset);  
  
    // @return the value associated with $offset  
    function offsetGet($offset);  
  
    // associate $value with $offset (store the data)  
    function offsetSet($offset, $value);  
  
    // unset the data associated with $offset  
    function offsetUnset($offset);  
}
```

ArrayAccess

ArrayAccess does not allow references
(the following is an error)

```
class MyArray extends ArrayAccess {  
    function &offsetGet($offset) /* ... */  
    function offsetSet($offset, &$value) { /* ... */ }  
    function offsetExists($offset) { /* ... */ }  
    function offsetUnset($offset) { /* ... */ }  
}
```

ArrayAccess Example

- þ We want to create variables which can be shared between processes.
- þ We will set up interception so that access attempts on the variable are actually performed through a DBM file.

Binding Access to a DBM

```
<?php
class DbaAccess implements ArrayAccess {
    protected $db = NULL;
    function __construct($file, $handler) {
        if (!$this->db = dba_open($file, 'cd', $handler))
            throw new exception('Could not open file ' . $file);
    }
    function __destruct() { dba_close($this->db); }
    function offsetExists($offset) {
        return dba_exists($offset, $this->db);
    }
    function offsetGet($offset) {
        return dba_fetch($offset, $this->db);
    }
    function offsetSet($offset, $value) {
        return dba_replace($offset, $value, $this->db);
    }
    function offsetUnset($offset) {
        return dba_delete($offset, $this->db);
    }
}
?>
```

A Trivial Example

```
<?php
if (!class_exists('DbaReader', false)) {
    require_once 'dbadeader.inc';
}
$_SHARED = new DbaAccess('/tmp/.counter', 'flatfile');
$_SHARED['counter'] += 1;
printf("PID: %d\nCOUNTER: %d\n", getmypid(),
    $_SHARED['counter']);
?>
```

Iterators

- ⦿ Normal objects behave like arrays when used with the **foreach** construct
- ⦿ Specialized Iterator objects can be iterated differently

```
<?php

class Object {
    public $prop1 = "Hello ";
    public $prop2 = "World\n";
}

foreach(new Object as $prop) {
    echo $prop;
}

?>
```

What are Iterators

- þ Iterators are a concept to iterate anything that contains other things.
- þ Iterators allow to encapsulate algorithms

What are Iterators

¶

Iterators are a concept to iterate anything that contains other things. Examples:

- ¶ Values and Keys in an array [ArrayObject](#), [ArrayIterator](#)
- ¶ Text lines in a file [SplFileObject](#)
- ¶ Files in a directory [\[Recursive\]DirectoryIterator](#)
- ¶ XML Elements or Attributes [ext: SimpleXML, DOM](#)
- ¶ Database query results [ext: PDO, SQLite, MySQLi](#)
- ¶ Dates in a calendar range [PECL/date \(?\)](#)
- ¶ Bits in an image ?

¶

Iterators allow to encapsulate algorithms

What are Iterators

¶

Iterators are a concept to iterate anything that contains other things. Examples:

- ¶ Values and Keys in an array `ArrayObject`, `Iterator`
- ¶ Text lines in a file `SplFileObject`
- ¶ Files in a directory `[Recursive]DirectoryIterator`
- ¶ XML Elements or Attributes `ext: SimpleXML`, `DOM`
- ¶ Database query results `ext: PDO`, `SQLite`, `MySQLi`
- ¶ Dates in a calendar range `PECL/date (?)`
- ¶ Bits in an image ?

¶

Iterators allow to encapsulate algorithms

¶ Classes and Interfaces provided by SPL:

`AppendIterator`, `CachingIterator`, `LimitIterator`,
`FilterIterator`, `EmptyIterator`, `InfiniteIterator`,
`NoRewindIterator`, `OuterIterator`, `ParentIterator`,
`RecursiveIterator`, `RecursiveIteratorIterator`,
`SeekableIterator`, `SplFileObject`, ...

Array vs. Iterator

An array in PHP

- þ can be rewound:
- þ is valid unless it's key is NULL:
- þ have current values:
- þ have keys:
- þ can be forwarded:

```
$ar = array()  
reset($ar)  
!is_null(key($ar))  
current($ar)  
key($ar)  
next($ar)
```

Something that is traversable

- þ may know how to be rewound:
(does not return the element)
- þ should know if there is a value:
- þ may have a current value:
- þ may have a key:
(may return NULL at any time)
- þ can forward to its next element:

```
$it = new Iterator;  
$it->rewind()  
  
$it->valid()  
$it->current()  
$it->key()  
  
$it->next()
```

The big difference

Arrays

- require memory for all elements
- allow to access any element directly

Iterators

- only know one element at a time
- only require memory for the current element
- forward access only
- Access done by method calls

Containers

- require memory for all elements
- allow to access any element directly
- can create external Iterators or are internal Iterators

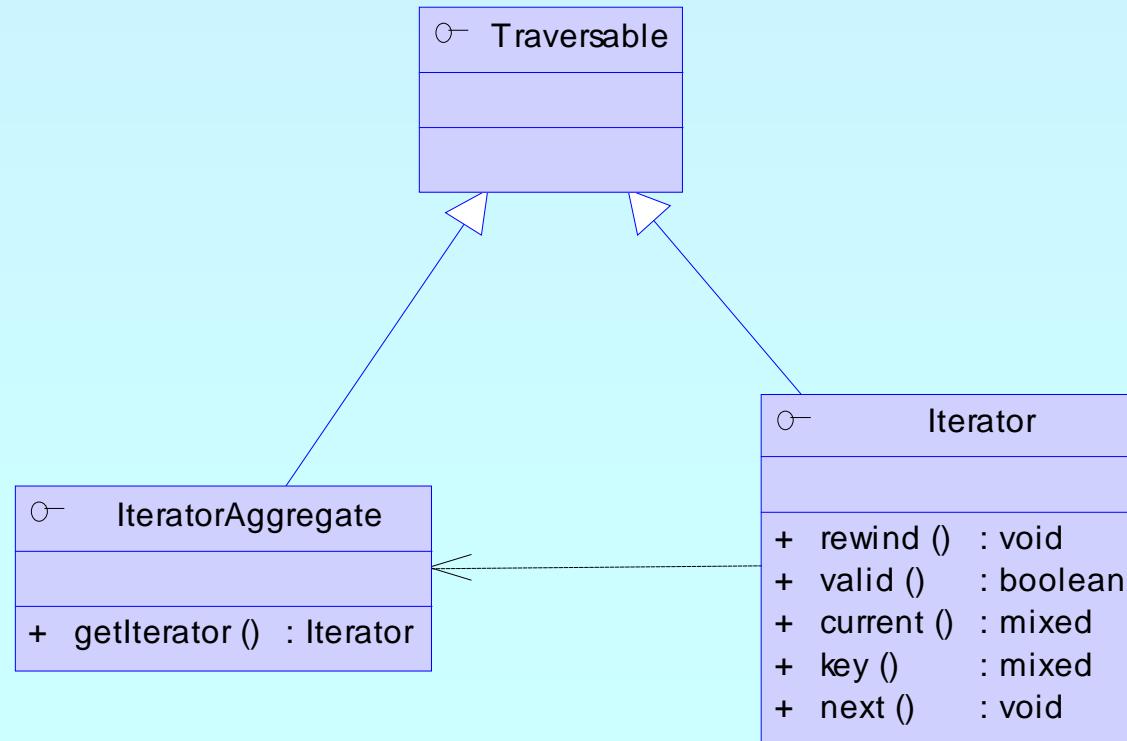

The basic concepts

- þ Iterators can be internal or external
also referred to as active or passive
- þ An internal iterator modifies the object itself
- þ An external iterator points to another object
without modifying it
- þ PHP always uses external iterators at engine-level
- þ Iterators **may** iterate over other iterators

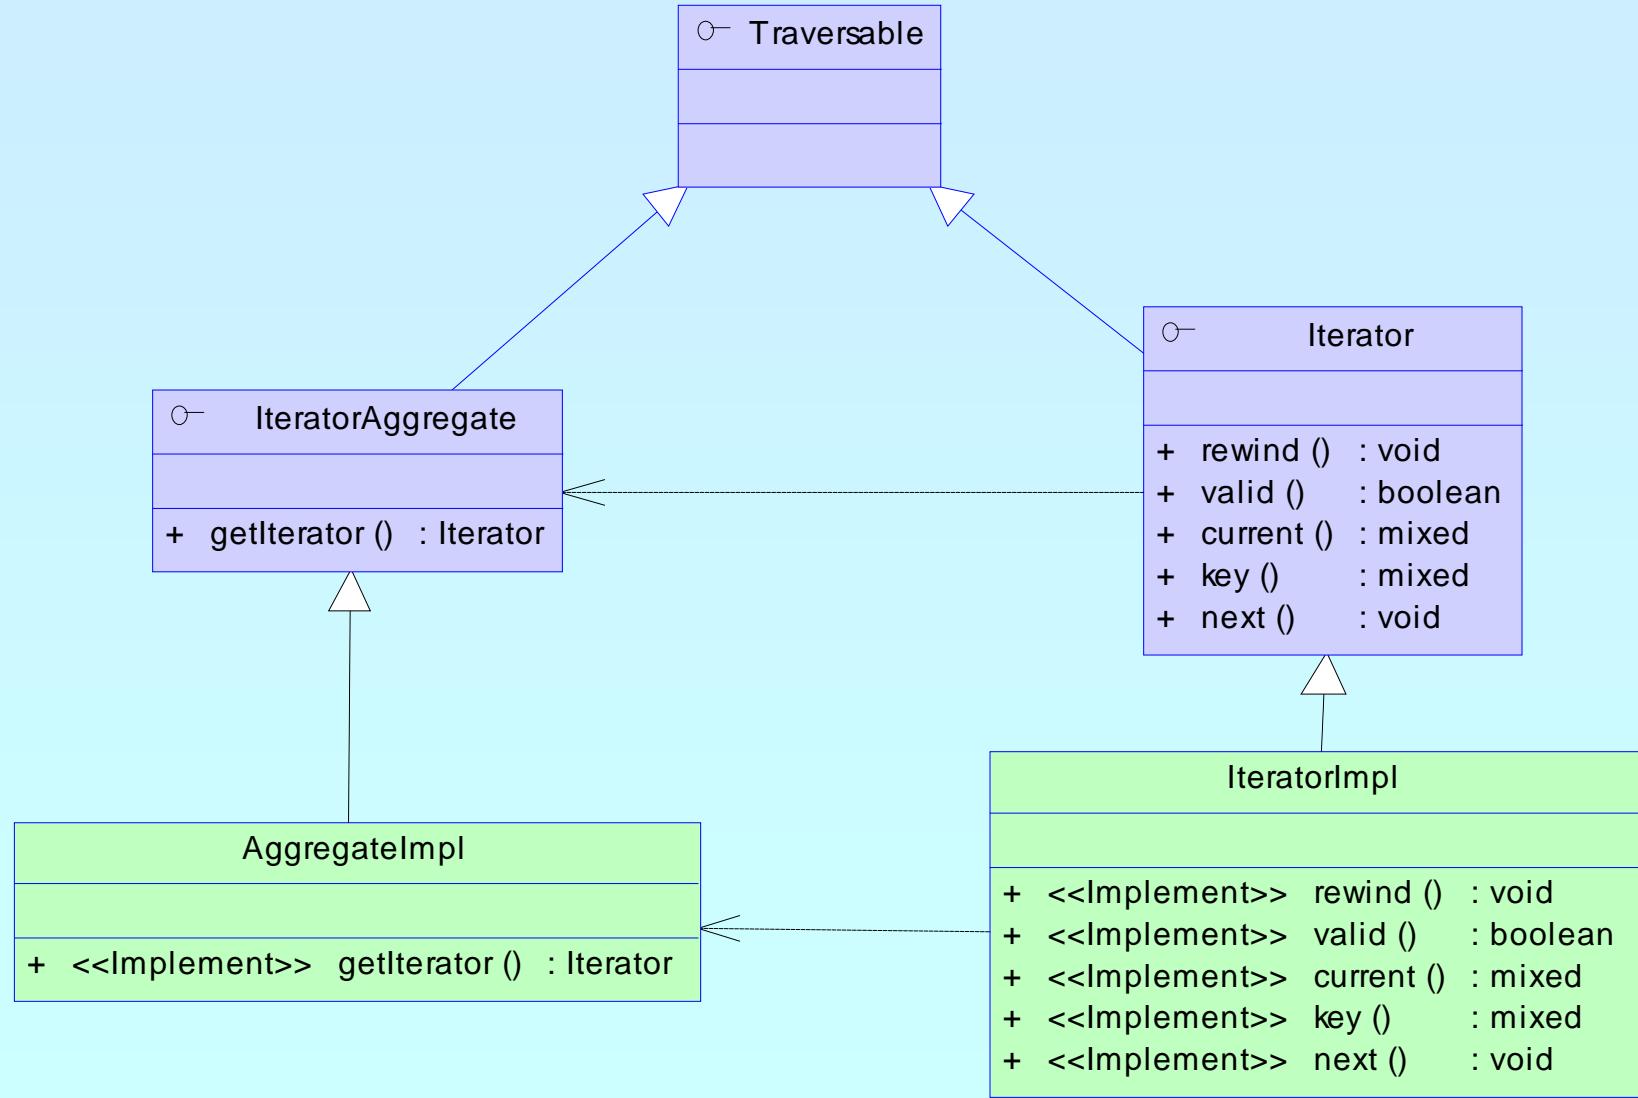

PHP Iterators

- þ Anything that can be iterated implements Traversable
- þ Objects implementing Traversable can be used in foreach
- þ User classes cannot implement Traversable
- þ IteratorAggregate is for objects that use external iterators
- þ Iterator is for internal traversal or external iterators

Implementing Iterators

How Iterators work

- Iterators can be used manually
- Iterators can be used implicitly with **foreach**

```
<?php
$o = new ArrayIterator(array(1, 2, 3));
$o->rewind();
while ($o->valid()) {
    $key = $o->key();
    $val = $o->current();
    // some code
    $o->next();
}
?>
```

```
<?php
$o = new ArrayIterator(array(1, 2, 3));
foreach($o as $key => $val) {
    // some code
}
?>
```

How Iterators work

- þ Internal Iterators
- þ User Iterators

```
<?php
interface Iterator {
    function rewind();
    function valid();
    function current();
    function key();
    function next();
}
?>
```

```
<?php
$it = get_resource();
for ($it->rewind(); $it->valid(); $it->next()) {
    $value = $it->current(); $key = $it->key();
}
?>
```

How Iterators work

- þ Internal Iterators
- þ User Iterators

```
<?php
interface Iterator {
    function rewind();
    function valid();
    function current();
    function key();
    function next();
}
?>
```

```
<?php
$it = get_resource();
foreach($it as $key=>$val) {
    // access data
}
?>
```

How Iterators work

þ
þ

Internal Iterators

User Iterators

```
<?php
interface Iterator {
    function rewind();
    function valid();
    function current();
    function key();
    function next();
}
?>
```

```
<?php
class FilterIterator implements Iterator {
    function __construct(Iterator $input)...
    function rewind()...
    function accept()...
    function valid()...
    function current()...
    function key()...
    function next()...
}
?>
```

```
<?php
$it = get_resource();
foreach(new Filter($it, $filter_param) as $key=>$val) {
    // access filtered data only
}
?>
```

Debug Session

```
<?php
class ArrayIterator {
    protected $ar;
    function __construct(Array $ar) {
        $this->ar = $ar;
    }
    function rewind() {
        rewind($this->ar);
    }
    function valid() {
        return !is_null(key($this->ar));
    }
    function key() {
        return key($this->ar);
    }
    function current() {
        return current($this->ar);
    }
    function next() {
        next($this->ar);
    }
}
?>
```

PHP 5.1

```
<?php
$sa = array(1, 2, 3);
$o = new ArrayIterator($sa);
foreach($o as $key => $val) {
    echo "$key => $val\n";
}
?>
```

```
0 => 1
1 => 2
2 => 3
```

Aren't Iterators Pointless in PHP?

- þ Why not just use arrays:
`foreach($some_array as $item) { /*...*/}`
- þ Aren't we making life more difficult than need be?
- þ No! For simple aggregations the above works fine (though it's slow), but not everything is an array.

What about:

- þ Buffered result sets
- þ Lazy Initialization
- þ Directories
- þ Anything not already an array

Iterators by example

- þ Using Iterators you can efficiently grab all groups from INI files
- þ The building blocks:
 - þ A class that handles INI files
 - þ An abstract filter Iterator
 - þ A filter that filters group names from the INI file input
 - þ An Iterator to read all entries in the INI file
 - þ Another filter that allow to search for specific groups

INI file abstraction

```
// Remember DbaAccess from page 86?  
  
// class DbaAccess implements ArrayAccess ...  
  
class DbaReader extends DbaAccess implements Iterator {  
    private $key = false, $val = false;  
  
    private function fetch_data($key) {  
        if (($this->key == $key) != false)  
            $this->val = dba_fetch($this->key, $this->db);  
    }  
    function rewind() {  
        $this->fetch_data(dba_firstkey($this->db));  
    }  
    function next() {  
        $this->fetch_data(dba_nextkey($this->db));  
    }  
    function current() { return $this->val; }  
    function valid() { return $this->key != false; }  
    function key() { return $this->key; }  
}  
  
class IniFile extends DbaReader {  
    function __construct($filename) {  
        parent::__construct($filename, 'ini file');  
    }  
}
```

Filtering Iterator keys

FilterIterator is an abstract class

- ↳ Abstract accept() is called from rewind() and next()
- ↳ When accept() returns false next() will be called automatically

```
<?php
class KeyFilter extends FilterIterator
{
    private $rx;

    function __construct(Iterator $it, $regex) {
        parent::__construct($it);
        $this->rx = $regex;
    }
    function accept() {
        return ereg($this->rx, $this->getInnerIterator()->key());
    }
    function getRegex() {
        return $this->rx;
    }
    protected function __clone($that) {
        // disallow clone
    }
}
?>
```

Getting only INI groups

```
<?php
if (!class_exists('KeyFilter', false)) {
    require_once('keyfilter.inc');
}

class IniGroups extends KeyFilter {
    function __construct($filename) {
        parent::__construct(
            new IniFile($filename, '^\\[.*\\]$'));
    }
    function current() {
        return substr(parent::key(), 1, -1);
    }
    function key() {
        return substr(parent::key(), 1, -1);
    }
}
?>
```

Putting it to work

```
<?php

if (!class_exists('KeyFilter', false)) {
    require_once('keyfilter.inc');
}

if (!class_exists('IniGroups', false)) {
    require_once('ini groups.inc');
}

$it = new IniGroups($argv[1]);

if ($argc > 2) {
    $it = new KeyFilter($it, $argv[2]);
}

foreach($it as $group) {
    echo $group . "\n";
}

?>
```

Avoid calling
__autoload()

Conclusion so far

- þ Iterators require a new way of programming
- þ Iterators allow to implement algorithms abstracted from data
- þ Iterators promote code reuse
- þ Some things are already in SPL
 - þ Filtering
 - þ Handling recursion
 - þ Limiting
- þ The above are all “*Decorator*” patterns

Design Patterns

Let's Talk About Patterns

- þ Patterns catalog solutions to problem categories
- þ They consist of
 - þ A name
 - þ A description of their problem
 - þ A description of the solution
 - þ An assessment of the pros and cons of the pattern

What do patterns have to do with OOP?

- þ Not so much.

- Patterns sources outside OOP include:

- þ Architecture (the originator of the paradigm)
- þ User Interface Design (wizards, cookie crumbs, tabs)
- þ Cooking (braising, pickling)

Patterns We've Seen So Far

- þ Singleton Pattern
- þ Proxy Pattern
- þ Iterator Pattern
- þ Decorator Pattern
- þ Factory Pattern

Aggregator Pattern

Problem: You have collections of items that you operate on frequently with lots of repeated code.

Remember our calendars:

```
foreach($entries as $entry) {  
    echo $entry;  
}
```

Solution: Create a container that implements the same interface, and performs the iteration for you.

Aggregator Pattern

```
class EntryAggregate extends Entry {  
    protected $entries;  
    ...  
    public function display() {  
        foreach($this->entries as $entry) {  
            $entry->display();  
        }  
    }  
    public function add(Entry $e) {  
        array_push($this->entries, $e);  
    }  
}
```

þ

By extending `Entry`, the aggregate can actually stand in any place that entry did, and can itself contain other aggregated collections.

Proxy Pattern

- þ ***Problem:*** You need to provide access to an object, but it has an interface you don't know at compile time.
- þ ***Solution:*** Use accessor/method overloading to dynamically dispatch methods to the object.
- þ ***Discussion:*** This is very typical of RPC-type facilities like SOAP where you can interface with the service by reading in a definitions file of some sort at runtime.

Proxy Pattern in PEAR SOAP

```
<?php
class SOAP_Client {
    public $wsdl;
    public function __construct($endpoint) {
        $this->wsdl = WSDLManager::get($endpoint);
    }
    public function __call($method, $args) {
        $port = $this->wsdl->getPortForOperation($method);
        $this->endpoint = $this->wsdl->getPortEndpoint($port);
        $request = SOAP_Envelope::request($this->wsdl);
        $request->addMethod($method, $args);
        $data = $request->saveXML();
        return SOAP_Envelope::parse($this->endpoint, $data);
    }
}
?>
```

Decorator Pattern

Problem: You have a class that does – more or less – what you need. But you need a few tweaks.

Solution: Write a class that works like a proxy, but all at compile time. So in the end, to the user, your new class looks exactly like old one. And mostly does the same. That is, because most calls are just passed through. But in some “stubs” you do some work.

Discussion: We have seen a few examples with Iterators. We could think here of a two column view with left column showing odd and right showing even entries. Easy for a Decorator.

Observer Pattern

þ

Problem: You want an object to automatically notify dependents when it is updated.

þ

Solution: Allow 'observer' to register themselves with the observable object.

þ

Discussion: An object may not apriori know who might be interested in it. The Observer pattern allows objects to register their interest and supply a notification method.

Object handling side notes

þ

You cannot access the object identifier/handle

```
$observers[] = $observer;
```

þ

YOU need to prevent double insertion/execution

```
foreach($observers as $o) {  
    if ($o === $observer) return;  
}  
$observers[] = $observer;
```

þ

No easy way to delete an object from an array

```
foreach($observers as $k => $o) {  
    if ($o === $observer) {  
        unset($observer[$k]);  
        break;  
    }  
}
```

Object Storage

```
class ObjectStorage {
    protected $storage = array();

    function attach($obj) {
        foreach($this->storage as $o) {
            if ($o === $obj) return;
        }
        $this->storage[] = $obj;
    }

    function detach($obj) {
        foreach($this->storage as $k => $o) {
            if ($o === $obj) {
                unset($this->storage[$k]);
                return;
            }
        }
    }
}
```

Object Storage in 5.2

```
class ObjectStorage {
    protected $storage = array();

    function attach($obj) {
        $this->storage[spl_object_hash($obj)] = $obj;
    }

    function detach($obj) {
        unset($this->storage[spl_object_hash($obj)]);
    }
}
```

Or simply use `SplObjectStorage`

Observer Pattern Implementation

```
class MySubject implements Subject {
    protected $observers;
    public function __construct() {
        $this->observer = new ObjectStorage;
    }
    public function attach(Observer $o) {
        $this->observers->attach($o);
    }
    public function detach(Observer $o) {
        $this->observers->detach($o);
    }
    public function notify() {
        foreach($this->observers as $o) $o->update($this);
    }
}
class MyObserver implements Observer {
    public function update(Subject $s) {
        // do logging or some other action
    }
}
```

Concrete Examples: logging facilities: email, debugging, SOAP message notifications.

Mock Pattern

þ

Problem: Need to replace a complex structure with something easy for testing or error handling? Or when building an offline version of your app?

þ

Solution: Extract the protocol between user (your app) and the structure (e.g. database). Then write this as an Interface and provide multiple implementations with different backends.

þ

Discussion: Often “stuff” just grows. When using an interface we are limiting ourselves. Because a change to the interface has to be applied to all implementations.

Mocks & Dependency Injection

```
interface DataAccess extends ArrayAccess {
    function connect($connection);
    // function offsetGet($offset);
    // function offsetSet($offset, $value);
    // function offsetExists($offset);
    // function offsetUnset($offset);
}

// class DbaAccess from page 86 again
class DbaData extends DbaAccess implements DataAccess {
    function __construct() {
        parent::__construct('/dev/null', 'ini file');
    }
    function connect(Array $connection) {
        $connection = split(':', $connection);
        $this->db = dba_open($connection[0] 'cd', $connection[1]));
    }
}

class app {
    function __construct(DataAccess $db) {
        $this->db = $db;
        $db->connect('/usr/local/myfile.db4:db4');
    }
}
```

Mocks & Dependency Injection

```
interface DataAccess extends ArrayAccess {
    function connect($connection);
    // function offsetGet($offset);
    // function offsetSet($offset, $value);
    // function offsetExists($offset);
    // function offsetUnset($offset);
}

// How about some test data you can rely on?
class TestData extends ArrayObject implements DataAccess {
    function connect($filename) {
        $this['key1'] = 'value1';
        $this['key2'] = 'value2';
        $this['key3'] = 'value3';
        $this['key4'] = 'value4';
        $this['key5'] = 'value5';
    }
}

class app {
    function __construct(DataAccess $db) {
        $this->db = $db;
        $db->connect('/usr/local/myfile.db4:db4');
    }
}
```

At Last some Hints

- þ List of all SPL classes PHP 5.0.0
`php -r 'print_r(array_keys(spl_classes()));'`
- þ Reflection of a built-in class PHP 5.1.2
`php --rc <Class>`
- þ Reflection of a function or method PHP 5.1.2
`php --rf <Function>`
- þ Reflection of a loaded extension PHP 5.1.2
`php --re <Extension>`
- þ Extension information/configuration PHP 5.2.2
`php --ri <Extension>`
